TECHNICAL HANDBOOK - DATA SUMMARY

Note: This regulation supersedes Tests Y 800, Issue 1, dated 20 Mar 50 and Tests Y 810, Issue 1, dated 4 Feb 54.

TESTER, VALVE, AVO, NO 1

PURPOSE
To test standard British and American valves for emission, mutual conductance, heater continuity, cathode-heater insulation when hot and inter-electrode insulation when cold.

DESCRIPTION
The tester consists of a main unit and a subsidiary unit, connected together by a nine-core cable. The main unit contains the power supplies, selector switches and indicating meter. The subsidiary unit contains 12 types of valve holder, a rotary selector switch and an auto-transformer.

PERFORMANCE

The voltages which can be applied to a valve under test are:

- Anode: from 12V in seven steps to 250V
- Screen: from 60V in seven steps to 250V
- Heater: from 2V in fourteen steps to 40V or from 0.28V to 5.6V

POWER REQUIREMENTS AND CONSUMPTION

200 - 250V, 50c/s single-phase, a.c. supply
Consumption 30VA approximately.

PURPOSE

To test standard British and American valves under conditions corresponding precisely to any desired set of d.c. electrode voltages. Checks on inter-electrode insulation and heater continuity can be made with the valve cold or at working temperature.

DESCRIPTION

The tester is built into a case enabling any normal valve to be plugged into the valve holder panel and a variety of tests applied as detailed below. A polarised relay is incorporated which prevents damage to the instrument due to overloading the h.t. circuits. It will, in most cases, save the heater of a valve to which the h.t. or screen voltage has been inadvertently applied. Operation of the cut-out is shown by failure of the meter illumination. Heater voltages up to 120V are available.

APPLIED TESTS

Inter-electrode insulation and heater continuity:-

Faulty insulation between valve electrodes with heater hot or cold is shown on the resistance scale of the meter, the electrodes between which break down occurs being directly indicated.

Breakdown of cathode or filament to other electrodes.

Issue 1, 18 Feb 58
Cathode/heater insulation:-

Cathode/heater insulation is measured with the heater hot.

Valve characteristics:-

The anode current of a valve can be measured at anode voltages from 20 to 400V, in sixteen steps, screen voltages from 20 to 300V, in sixteen steps, and with any value of negative grid bias to -100V. Complete 3A/V, 3V/A, characteristics can therefore be drawn. Similar characteristics can be taken for screen current. Amplification factor and anode a.c. resistance may be derived. Direct measurement of mutual conductance in mA/V at any available electrode voltages. Mutual conductance comparison tests with the rated figure, on a coloured 'good/bad' scale. Press button 'gas' test shows the presence of grid current, the value in \( \mu A \) being computed in terms of anode current change. Four meter ranges are provided, i.e., 2.5\( \mu A \), 10\( \mu A \), 20\( \mu A \) and 100\( \mu A \) respectively, and similar ranges of mutual conductance in mA/V.

Rectifying valves:-

Tested under full load conditions with 8mA reservoir condenser. Current loads of 8mA, 16mA, 32mA, 64mA and 128mA are available for each anode, the efficiency of the rectifier at these load conditions being directly shown on a 'good/bad' scale. A d.c. load condition of 1mA is used when signal diodes are under test. A removable link in the anode circuit allows the use of external metering.

the testing of valves under load conditions or the adoption of the equipment to test specialized, non-standard types of valve not catered for in normal circuit arrangements.

TESTER, VALVE, AVO, CT160

PURPOSE

To test standard British and American valves and valves of disc seal and flying lead types under conditions corresponding precisely to any desired set of d.c. electrode voltages. To give a rapid diagnosis of the condition of a valve on a 'good/bad' basis.

DESCRIPTION

The instrument is housed in a robust metal suitcase. It is readily portable and waterproof. In the lower half, a metal panel is fitted on which is mounted the
power supplies and the majority of the controls. The upper part, or lid, houses the valve holder panel and a rotary selector switch. A relay is incorporated which prevents damage to the instrument due to an inadvertent overload of the h.t. circuits. Both visual and audible warning is given when the 'cut-out' operates. Two eleven-position switches provide combinations of voltages for anode and screen electrodes, 20 - 400V for anode, 20 - 300V for screen. Variable bias from 0 - 40V and 32 heater voltages from 0,025V to 11V are available. The instrument is supplied with a mains input lead and two 14 inch 'wander' leads, for use with the nine-socket terminal board.

TEST APPLIED BY INSTRUMENT

Direct meter indication of heater continuity, insulation resistance between individual electrodes, with the valve cold, or between heater strapped to cathode and all the other electrodes strapped together, with the valve hot. Direct meter indication of cathode to heater insulation, with the valve hot. Direct indication of anode current and mutual conductance at pre-determined combination of h.t. and g.b. voltages. Measurement of control grid current directly in uA.

Fig 3 - Tester, valve, Avo - CT 160
Rectifiers, both half and full wave, tested under reservoir capacitor conditions and switched d.c. loads from 200 V to 1200 V are available. A suitable d.c. load can also be selected for signal diodes on test. A colored scale gives direct indication of valve 'goodness' when 'batch' testing. Valve characteristic curves can be drawn over a range of applied electrode voltages, and data thus determined. By the use of the removable links in the anode circuits of the instrument, valves can be tested under load conditions. In the same way external metering can be used to read the required anode currents or the instrument adapted for making tests on specialized, non-standard types of valve not catered for in normal circuit arrangements.
